CITY, TOWN

Denver

STATE

Colorado
The Beaver Creek Bridge is on Route 87 which winds through Wind Cave National Park. The bridge spans Beaver Creek which is north of the administrative headquarters area.

A steel reinforced concrete bridge, the Beaver Creek Bridge is comprised of two parallel arches which carry the 20 support struts of the deck. The arches end in two main piers, which rest on the rock walls of the ravine. The deck itself curves in a gentle S.

The arch spans 120 feet and rises 115 feet above the ravine floor. The north end of the bridge has a 20-foot approach which curves 60° to the northwest. A 40° curve connects the 23-foot southern approach. The square struts, which rest on the arch, end in four arched supports. The north and south supports form an arched spandrel, while the east and west supports protrude slightly beyond the edge of the deck. A handrail or guardrail runs along the edge of the deck. The rail and deck are, in part, cantilevered out from the main support piers.

The 1977 Bridge Safety Inspection Report considers the conditions of the bridge to be good.

The boundary for the bridge includes only the northern 20-foot approach, the 120-foot long bridge and the 23-foot southern approach. The adjoining road, Route 87, is not considered part of the engineering significance.
Beaver Creek Bridge is the largest and most complex reinforced concrete bridge of its size in the state. There were no concrete bridges of this design, size, and complexity until the 1960s in South Dakota. Among the recorded bridges it is unique, and is, therefore, highly significant as an engineering site at the state level under Criteria C.

Concrete arch bridge construction was developed around 1900. Masonry arch bridges had had a long history, but improvements in concrete technology led to this significant development. In South Dakota concrete was used in bridge construction from c. 1900 on. Two large cement plants in the state, including the Western Portland Cement Company, founded in 1891, produced most of the cement. The earliest use in bridge building was as a foundations, footings, and pilings for the metal truss spans, which were used extensively between 1905 and 1920. The truss bridges were used to span large expanses such as the Missouri River and shorter spaces such as secondary roads over the James River. In the 1930s concrete was used for small bridges all across the state. Small arch, bowstring, and cast post- and lintel type bridges were built with Federal assistance. Most were built on secondary roads, spanning creek ditches and shallow ravines. Freeway construction in the 1960s expanded concrete bridge technology into large, complex structures.

Construction engineer, Morris E. Adelstein, faced a difficult site and found an elegant solution. The bridge not only spans a deep, rugged ravine, but curves in a "S" shape to connect with the road on either side. Adelstein's bridge was in keeping with the Park Service's philosophy of complimentary and unobtrusive design. A civil engineer who worked with the Northwest Engineering Company in nearby Rapid City, Adelstein was one of the earliest registered engineers and land surveyors in South Dakota.

8. Statement of Significance

Applicable National Register Criteria

X A Property is associated with events that have made a significant contribution to the broad patterns of our history.

___ B Property is associated with the lives of persons significant in our past.

X C Property embodies the distinctive characteristics of a type, period, or method of construction or represents the work of a master, or possesses high artistic values, or represents a significant and distinguishable entity whose components lack individual distinction.

___ D Property has yielded, or is likely to yield information important in prehistory or history.

Criteria Considerations

___ A owned by a religious institution or used for religious purposes.
___ B removed from its original location.
___ C a birthplace or a grave.
___ D a cemetery.
___ E a reconstructed building, object, or structure.
___ F a commemorative property.
___ G less than 50 years of age or achieved significance within the past 50 years.

**Township, Range, Section:** T5S R5E, Sec 26

**Verbal Boundary Description:** The bridge structure and the northern and southern approaches from the boundary. The boundary begins at the 20 foot approach on the north end, includes the 120 foot bridge and end 23 feet further south at the beginning of the southern approach.

**Boundary Justification:** Because the bridge is located on a public road, there are no legal boundary lines for the ends of the bridge. Therefore, these boundaries are drawn to encompass only the superstructure and substructure of the bridge itself. The adjoining road, Route 87, is not considered part of the engineering significance.

Beaver Creek Bridge, Wind Cave National Park, Custer County, SD

Narrative Description

Summary:
Built in 1929, the Beaver Creek Bridge is located on SD Highway 87 approximately a half mile from the junction of US Highway 385 and SD Highway 87. The bridge spans Beaver Creek Canyon, and the deck of the bridge is roughly 115 feet above the canyon floor.

Setting:
This bridge is a 225' linear feature which runs approximately north-south. The structure spans the Beaver Creek canyon the floor of which is roughly 115 feet below the bridge deck. Beaver Creek canyon is a wooded ravine with a small stream, Beaver Creek, meandering through the bottom. The canyon, or ravine, has steep sides with numerous rock outcroppings. A heavy stand of ponderosa pine is found on the upper margins of the canyon with boxelder, cottonwood, elm and other deciduous trees found in the canyon bottom. The highway is a sinuous two lane paved thoroughfare.

Description:
The open spandrel deck arch bridge has one main span with a steel stringer approach span at each end. The 120 foot main span sits on concrete piers. In addition to the main span there are two steel stringer approach spans, with outer concrete girders, at each end. The approach spans sit on the main span’s pier, a concrete pier, and a solid abutment with curved wing walls. The single arch span of this bridge is a two-ribbed open spandrel arch. The ribs are connected with concrete bridging. The arches spring from the bottom of massive concrete piers. Ten concrete columns rest on each rib and support the concrete floor beams. Between the floor beams are longitudinal concrete stringers. The beams are cantilevered to carry the concrete deck and balustrade. The beams and stringers turn down at the columns to form decorative, ribbed column capitals. The approach spans are similar in configuration but the distance between the piers and abutment is greater than between the columns and main span. The approach spans have steel I-beam stringers which are supported by the concrete floor beams. The approach spans of both ends of the bridge curve; the south span curves to the right, and the north span curves to the left. The railing is a concrete balustrade with a panel between each vertical support (Traeger and Rosby 1990:6).

The road surface is 20 feet wide, the north end uses "two twenty-foot long approach spans on a sixty-degree curve to the right while the south end reaches to land by means of three twenty foot approach spans on a forty degree curve to the left" (Hamilton 1930: 137).
Beaver Creek Bridge, Wind Cave National Park, Custer County, SD

Narrative Description (continued)

Historical Information:
The Beaver Creek Bridge was designed by J. Harper Hamilton, the State Bridge Engineer for South Dakota. Morris E. Adelstein was the construction engineer for Northwestern Engineering Company. It was built by Northwestern Engineering Company, with Jack Linder serving as foreman on the project. The cost of the bridge was $25,000.

An article on "The Beaver Creek Bridge" written by J. Harper Hamilton, State Bridge Engineer, says that this bridge was part of the development of the State Game Park. Included in the planning of this bridge were J. Harper Hamilton, Park Superintendent Robertson, and C.E. Smith Engineer for the Park Board. In Hamilton's article on the bridge he notes that the "two arch ribs are thirty-two inches square at the crown and thirty-two inches wide by six feet deep at the springing lines" (1930:137). A part of the design has the arches "well embedded in the solid rock of the canyon sides" and it was explained that this was done more for the aesthetic of having the bridge arch appear to rise out of solid rock rather than have a visible junction of the concrete bridge arch and the natural stone wall.

(The following information is taken from Hamilton's article.) The falsework was constructed from timbers obtained locally. They were pine logs varying in length from twenty-four to fifty feet. They were lowered by means of the cable of a hoist carried out on a trolley line which was anchored into both sides of the canyon. The trolley line was a three-quarter inch plow steel cable held in the sides of the canyon by means of concrete dead men, three feet square and three feet deep, in which were imbedded eyes made of one inch steel. Many of the individual logs handled by this means weighed several tons.

The falsework logs were held in place by one and three quarter inch steel dowels which were set into solid rock and driven into the bottom of each log about eighteen inches. The logs wherever possible were set in a true vertical plane. The tops were cut off square and another dowel placed in the upper end, this latter dowel projecting up into the log above. The falsework was braced and cross braced by means of three by twelve bridge planks bolted in place. All bolts used were three quarters of an inch in diameter with malleable washers. These bolts facilitated the dismantling of the falsework and the removal of the planks with a minimum of damage to the lumber. All forms were made of selected lumber, chosen long before needed. In order to avoid warping they were oiled immediately after being built and kept under cover until needed in the construction.
Beaver Creek Bridge, Wind Cave National Park, Custer County, SD

Narrative Description (continued)

There were no available roads for crossing the canyon on account of the steepness of its walls and its great depth, and since it was necessary to travel twelve miles to get from one side of the canyon to the other, it was desirable that two separate mixing plants be placed on the project so that the pouring of concrete in the ribs could proceed from both sides simultaneously.

The specifications called for the arch ribs to be poured in one continuous operation and this required some of the work to be done at night. A temporary lighting system which worked satisfactorily, was arranged by the use of the old fashioned gasoline torches seen so often around circuses during their night shows. As the concrete was placed on the falsework, careful observations were made to determine the occurrence of any settlement. No settlement of any kind was noted.

An average crew of twenty men started the construction of this bridge on June 15th, 1929, and completed the last panel of handrail on November 15th of the same year. The quantities involved in this structure were principally four hundred and forty cubic yards of concrete and sixty-four thousand pounds of steel (Hamilton 1930:140).

This bridge was inventoried in 1975 by Lance J. Olivieri of the National Park Service, in 1977 in a Federal Highway Administration Bridge Safety Inspection Report, in 1982 by Carolyn Torma of the South Dakota Historical Preservation Center, and again in 1990 by Jennifer Traeger and Wayne Rosby of Renewable Technologies, Inc., Butte, Montana. In 1984 the bridge was listed on the National Register of Historic Places. In 1990 the Beaver Creek Bridge was included in the Historic Bridges in South Dakota multiple property listing.

In the original National Register nomination for the bridge, Morris E. Adelstein, was identified as the designer of the bridge. Documentation now indicates that Hamilton was the designer.

INTEGRITY STATEMENT: The integrity for the Beaver Creek Bridge is good. The 1990 inventory by Traeger and Rosby suggested the integrity was excellent at that time and there has been virtually no change. The Federal Highway Administration Bridge Safety Inspection Report indicated that there were numerous locations where the concrete was spalling but in terms of the integrity of the structure, this spalling is not significant. The only change in the bridge is resurfacing of the deck. This resurfacing had caused a "noticeable" rise in the road surface by approximately eight inches. In 1992 maintenance work included removing the built-up asphalt. This project added life to the bridge by removing several tons of
STATEMENT OF SIGNIFICANCE:
The Beaver Creek Bridge was previously listed as significant only under Criterion C for its engineering qualities. This amended submission documents that it is also significant under Criterion A for its association with politics/government and transportation. The Beaver Creek Bridge is significant at the state level under Criterion A for its association with the development of Wind Cave National Park. Wind Cave National Park was created in 1903 in an effort to protect it as an important natural feature, to make this resource more accessible, and to interpret the resource to a visiting public. At the time the bridge was built it was seen as providing an important transportation link between Wind Cave National Park to the south and the newly developing Custer State Park to the north. The Beaver Creek Bridge was made possible as a result of the efforts of South Dakota’s Senator Peter Norbeck. Senator Norbeck was the guiding force behind the creation and development of Custer State Park and the scenic highways within the park and the general vicinity.

The Beaver Creek Bridge is also significant at the state level under Criterion C due to its engineering significance. It has been identified as the only example of an open spandrel concrete arch bridge built in South Dakota (Rosby 1990). It is considered to be one of the three most significant bridges within the NPS’ Rocky Mountain Region (Olivieri 1975). It has also been called the largest and most complex reinforced concrete bridge [of its type] in the state. There were no concrete bridges of this design, size, and complexity until the 1960s in South Dakota. Among the recorded bridges it is unique, and is, therefore, highly significant as an engineering site at the state level under Criterion C. The period of significance extends from 1929, the bridge’s date of construction, to 1945, the end of the historic period as defined by the National Register.

Concrete arch bridge construction was developed around 1900. Masonry arch bridges had a long history, but improvements in concrete technology led to this significant development. In South Dakota concrete was used in bridge construction from c 1900 on. Two large cement plants in the state, including the Western Portland Cement Company, founded in 1891, produced most of the cement. The earliest use in bridge building was as foundations, footings, and pilings for the metal truss spans, which were used extensively between 1905 and 1920. The truss bridges were used to span large expanses such as the Missouri River and shorter spaces such as secondary roads over the James River. In the 1930s concrete was used for small bridges all across the state. Small arch, bowstring, and cast
Narrative Description (continued)

post-and-lintel type bridges were built with Federal assistance. Most were built
on secondary roads, spanning creek ditches and shallow ravines. Freeway
construction in the 1960s expanded concrete bridge technology into large, complex
structures.

Bridge engineer, J. H. Hamilton, faced a difficult site and found an elegant
solution. The bridge not only spans a deep, rugged ravine, but curves in a "S"
shape to connect with the road on either side. Hamilton's bridge was in keeping
with the Park Service's philosophy of complimentary and unobtrusive design.
Morris E. Adelstein, a civil engineer who worked with the Northwest Engineering
Company in nearby Rapid City, was one of the earliest registered engineers and
land surveyors in South Dakota. Adelstein was the construction engineer on the
Beaver Creek Bridge project.

The bridge has two metal plaques inscribed with the following "Beaver Creek
Bridge; 1929. Commissions; Governor W. J. Bulow, Chairman, J.B. Johnson, V.J.
Brown, Highway Engr.; Built by Northwestern Engineering Co., Rapid City, South
Dakota, Morris E. Adelstein, Const. Engr., J.A. Linder, Supt. of Const.; W.L.

The Beaver Creek Bridge was reevaluated under three historic contexts contained
in the Wind Cave National Park Multiple Property Submission (MPS): Recreation and
Tourism in the Black Hills and at Wind Cave, 1890-1945; Development and
Administration of Wind Cave National Park, 1903-1945; and National Park Service
Rustic Architecture and Public Works Construction, 1933-1942. (For additional
contextual information, refer to the MPS.)
